Tripwire

A testing guide. No terminal needed, just a browser.

https://tripwire.brainycyber.com

What this is

Tripwire compares the price of moving crypto between chains. Think Skyscanner, but for bridges.

Every 15 minutes it asks four bridges the same question: *"I hold X, I want Y, how much do I get?"* It compares each answer against the real market price and records the gap. A smaller gap means you keep more of your money.

On top of that sits an argument about NEAR, built from claims that re-check themselves against live data. If NEAR stops being the cheapest, the page says so. That is the point. An argument that cannot be proved wrong is just advertising.

Before you start

The numbers are live, so they will not match this guide exactly. You are checking that the app behaves correctly, not that it shows particular figures.

Test it page by page

1. Scoreboard	Four routes listed, cheapest at the top with a green "Best" tag. Change the corridor and the trade size. The table should update without the page reloading.
2. Spread	One line per route over time. Switch corridor and the chart redraws. Short lines early in a run are normal.
3. Size curve	Shows whether the cheap route stays cheap on a bigger trade. A gap in a line means that route did not quote that size.
4. Corridors	Who covers which routes. NEAR covers the most. Four corridors are served by NEAR alone.
5. Reliability	How often each route actually answers. The failure table should name real reasons, not one generic message.
6. Settlements	Real transactions pulled from the NEAR blockchain. No transaction should start with "demo".
7. Quote	Pick any two assets and any amount, then press Compare routes. It takes a few seconds because it asks every bridge live.

8. Thesis	Five claims with live values. Green means holding. Red means the argument needs revising.

Also worth checking

- Switch your device between light and dark mode. Everything should stay readable in both.
- Open it on a phone. Nothing should scroll sideways.
- Note the newest timestamp, wait 15 minutes, reload. It should have moved on its own.

Things that look wrong but are not

- **Zeros for a route on some corridors.** That route does not serve them. A gap in coverage is a real finding, not a bug.
- **"Awaiting data" on the thesis.** One claim needs settlement figures nobody has verified yet. It stays blank rather than assert a number we do not trust.
- **"Does not serve this corridor" on the Quote page.** Honest reporting. NEAR reaches 20 chains that the others here do not.

Every quote is a dry run. Nothing is ever signed, submitted or paid for, and no wallet is involved anywhere in the app.
